20. The QR-Algorithm

Recap: Last Time

We noted that eigenvalue revealing computations are generally divided into 2 phases; in **phase 1** we transform the matrix in into **Hessenberg form** in a finite number of steps, and in **phase 2** we apply a (possibly infinite) number of transformations to transform the Hessenberg matrix into **upper triangular form**

Where the "+"-entries are zeros if A is Hermitian $(A = A^*)$.

- Phase 1 Can be backwardly stably computed using a slightly modified version of the Householder-QR algorithm (making all the reflectors one element shorter, and applying Q_k from the left* and the right.)
- Phase 2 Instead of directly talking about phase 2, we looked at...
 - Rayleigh quotient (eigenvalue estimation).
 - Power iteration (only useful as a basis for...)
 - **Inverse iteration** (eigenvector estimation).
 - Rayleigh quotient iteration (eigenvalue and eigenvector estimation — cubically convergent).

Next, we look at the QR-algorithm, and make some connections with the ideas above.

The QR-Algorithm

The QR-algorithm can be viewed as a stable procedure for computing QR-factorizations of the matrix power A, A^2 , A^3 ,

Algorithm (The "Pure" QR-Algorithm)

```
The "Pure" QR-Algorithm \begin{split} \boldsymbol{A}^{(0)} &= \boldsymbol{A} \\ \text{for } k &= 1:\dots \\ \left[\boldsymbol{Q}^{(k)}, \boldsymbol{R}^{(k)}\right] &= \text{qr}\big(\boldsymbol{A}^{(k-1)}\big) \\ \boldsymbol{A}^{(k)} &= \boldsymbol{R}^{(k)}\boldsymbol{Q}^{(k)} \\ \text{endfor} \end{split}
```

Under suitable (non-restrictive) assumptions, this simple algorithm converges to a Schur form for the matrix A — Upper triangular if A is arbitrary, and diagonal if A is Hermitian.

Before we go any further, let us illustrate this numerically...

The QR-Algorithm: Applied to a Non-Hermitian A

∃ Movie

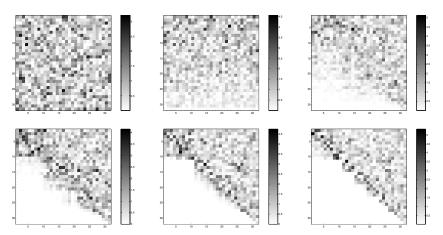

Figure: The QR-algorithm applied to a non-Hermitian matrix *A*. The panels show the initial matrix, and iterations 1, 4, 16, 32, and 64.

The QR-Algorithm: Applied to $A = A^*$

∃ Movie

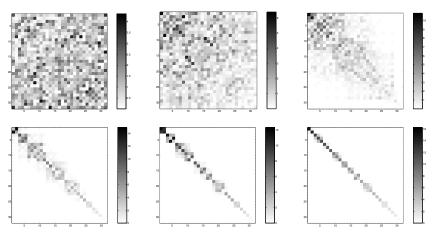

Figure: The QR-algorithm applied to a Hermitian matrix A. The panels show the initial matrix, and iterations 1, 4, 16, 32, and 64.

20. The QR-Algorithm

The QR-Algorithm: What Are We Doing???

Just a quick sanity-check... If QR = A, then

$$Q^*AQ = Q^*(QR)Q = (Q^*Q)RQ = RQ$$

Hence the matrices that we form are unitarily similar

$$A_{(k)} = Q_{(k)}^* \cdots Q_{(1)}^* A_{(0)} Q_{(1)} \cdots Q_{(k)}$$

In fact, this is the idea we had to reject in our effort to compute the Hessenberg form of A. Even though it has to be rejected as a **finite-step** method for transforming A, it turns out to be quite powerful as the basis of an iterative scheme.

As in the last lecture, in order to keep the discussion simple(r), we assume that $A \in \mathbb{R}^{m \times m}$, and $A = A^*$ so that $\lambda_k(A) \in \mathbb{R}$, and the set of eigenvectors is orthonormal.

The QR-Algorithm: Modifications

Since we will be applying the QR-algorithm to real symmetric matrices, we are looking for the diagonalization $\Lambda(A)$.

Like the Rayleigh quotient algorithm, the QR-algorithm (for real symmetric matrices) can be made to converge cubically. In order to achieve this, we must introduce three modifications

- 1. Before entering the iteration, A must be reduced to tri-diagonal form (using the "Hessenberg algorithm" (Phase#1)).
- 2. Instead of $A^{(k)}$, the **shifted matrix** $(A^{(k)} \mu^{(k)}I)$ is factored at each step, where $\mu^{(k)}$ is an eigenvalue estimate.
- 3. Whenever possible, and in particular whenever an eigenvalue is found, the problem is "deflated" by breaking $A^{(k)}$ into sub-matrices.

The Modified QR-Algorithm

Algorithm (Modified QR-Algorithm)

$$\begin{split} \mathbf{A}^{(0)} &= \text{hessenberg_form}(\mathbf{A}) \\ \delta &= \text{small tolerance} \sim \sqrt{\epsilon_{\text{mach}}} ? \\ \text{for k = 1:...} \\ &\quad \text{Select } \mu^{(k)} \\ &\quad \left[\mathbf{Q}^{(k)}, \mathbf{R}^{(k)} \right] = \text{qr} \big(\mathbf{A}^{(k-1)} - \mu^{(k)} \mathbf{I} \big) \\ &\quad \mathbf{A}^{(k)} &= \mathbf{R}^{(k)} \mathbf{Q}^{(k)} + \mu^{(k)} \mathbf{I} \\ \text{If any } |\mathbf{A}^{(k)}_{\mathbf{j},\mathbf{j}+1}| \leq \delta \text{ then} \\ &\quad \text{Set } \mathbf{A}^{(k)}_{\mathbf{j},\mathbf{j}+1} = \mathbf{A}^{(k)}_{\mathbf{j}+1,\mathbf{j}} = \mathbf{0} \text{, so that} \\ &\quad \left[\begin{array}{c} A^{(k)}_1 & 0 \\ 0 & A^{(k)}_2 \end{array} \right] = \mathbf{A}^{(k)} \end{split}$$

recursively apply the QR-algorithm to $A_1^{(k)}$ and $A_2^{(k)}$ endfor

The Modified QR-Algorithm: Components

- 1. We have already discussed reduction to Hessenberg form.
- 2. We will return to a discussion on selecting the shifts $\mu^{(k)}$.
- 3. We leave the discussion on deflation as "an exercise for the motivated student." (There are many details, e.g. pivoting to split the matrix exactly in "half," to be taken care of to make this step maximally efficient)

For now, we focus the discussion on the "pure" form of the QR-algorithm... We relate the QR-algorithm to another method — **simultaneous iteration** — whose behavior is more intuitive.

20. The QR-Algorithm

Unnormalized Simultaneous Iteration

The Idea: Apply the power iteration to several vectors at once.

Suppose we have a set of **linearly independent** vectors $\{v_1^{(0)}, \dots, v_n^{(0)}\}$, then the spaced spanned by the vectors $\{A^k \vec{v}_1^{(0)}, \dots, A^k \vec{v}_n^{(0)}\}$ generated by simultaneous power iteration, converges to the space spanned by the neigenvectors \vec{q}_k corresponding to the *n* abs-largest eigenvalues $|\lambda_k| > 0$, i.e.

$$\lim_{k\to\infty}\operatorname{span}\left(A^k\vec{v}_1^{(0)},\ldots,A^k\vec{v}_n^{(0)}\right)=\operatorname{span}\left(\vec{q}_1,\ldots,\vec{q}_n\right).$$

In matrix form

$$V^{(0)} = \left[\vec{v}_1^{(0)} \middle| \cdots \middle| \vec{v}_n^{(0)} \middle], \quad V^{(k)} = A^k V^{(0)} = \left[\vec{v}_1^{(k)} \middle| \cdots \middle| \vec{v}_n^{(k)} \middle] \right]$$

Unnormalized Simultaneous Iteration

Since we are interested in span $\left(A^k \vec{v}_1^{(0)}, \dots, A^k \vec{v}_n^{(0)}\right)$, *i.e.* the column-space of $V^{(k)}$ we compute the reduced QR-factorization

$$\widehat{Q}^{(k)}\widehat{R}^{(k)}=V^{(k)}.$$

We can justify that the columns of $\widehat{Q}^{(k)}$ converge to the eigenvectors \vec{q}_k ; if we write both $\vec{v}_j^{(0)}$ and $\vec{v}_j^{(k)}$ in term of the eigenvectors of A

$$\vec{v}_{j}^{(0)} = a_{1j}\vec{q}_{1} + \dots + a_{mj}\vec{q}_{m}$$

$$\vec{v}_{j}^{(k)} = \lambda_{1}^{k}a_{1j}\vec{q}_{1} + \dots + \lambda_{m}^{k}a_{mj}\vec{q}_{m}.$$

For simplicity (we can discuss eigenvectors rather than invariant (generalized) eigenspaces) we assume that the first n eigenvalues are distinct, and ordered so that

Assumption #1

$$|\lambda_1| > |\lambda_2| > \cdots > |\lambda_n| > |\lambda_{n+1}| \ge |\lambda_{n+2}| \ge \cdots \ge |\lambda_m|$$

We need one further assumption before we can state a theorem — Let \widehat{Q} be the $(m \times n)$ matrix whose columns are the eigenvectors \overrightarrow{q}_k . We need the following to be true

Assumption #2

All the leading principal sub-matrices of $\widehat{Q}^*V^{(0)}$ are non-singular.

A leading principal sub-matrix is anchored in the upper left corner (the m_{11} -element) and is a square matrix of size (1×1) , (2×2) , ..., $(n \times n)$.

With these assumptions we case say something about how the vectors generated by the simultaneous iteration converge to the eigenvectors.

Theorem

Suppose the iteration defined by

$$V^{(0)} = \begin{bmatrix} \vec{v}_1^{(0)} & \cdots & \vec{v}_n^{(0)} \end{bmatrix}, \quad V^{(k)} = A^k V^{(0)}, \quad \widehat{Q}^{(k)} \widehat{R}^{(k)} = V^{(k)}$$

is carried out, and that the assumptions (see slide 13 and 14) are satisfied. Then, as $k \to \infty$, the columns of the matrices $\widehat{Q}^{(k)}$ converge linearly to the eigenvectors of A

$$\|\vec{q}_j^{(k)} \mp \vec{q}_j\| = \mathcal{O}(c^k)$$

for each $j \in [1, n]$, where c < 1 is the constant

$$c = \max_{1 \le k < n} \left| \frac{\lambda_{k+1}}{\lambda_k} \right|.$$

We have a problem: As $k \to \infty$, all the vectors $\vec{v}_1^{(k)}, \ldots, \vec{v}_n^{(k)}$ in the unnormalized simultaneous iteration converge to the **same** dominant eigenvector $\vec{q}_1(A)$.

Even though $\operatorname{span}\left(\vec{v}_1^{(k)},\ldots,\vec{v}_n^{(k)}\right)$ converges to something useful, *i.e.* $\operatorname{span}\left(\vec{q}_1,\ldots,\vec{q}_n\right)$, these vectors constitute a **highly ill-conditioned basis** (nearly linearly dependent basis) for that space. For practical purposes this approach is useless.

The fix is straight-forward:

Necessary Improvement

We must **orthonormalize** the basis in **every iteration**. Instead of forming the sequence $V^{(k)}$, we form a sequence $Z^{(k)}$ with the same column spaces, but where $Z^{(k)}$ is orthonormal.

Algorithm (Simultaneous Iteration)

Let
$$\widehat{\mathbf{Q}}^{(0)} \in \mathbb{R}^{m \times n}$$
 with orthonormal columns for $k = 1: \dots$

$$\mathbf{Z}^{(k)} = \mathbf{A} \widehat{\mathbf{Q}}^{(k-1)}$$

$$\left[\mathbf{Q}^{(k)}, \mathbf{R}^{(k)}\right] = \text{qr} \big(\mathbf{Z}^{(k)}\big)$$
endfor

Clearly, the column spaces of $Q^{(k)}$ and $Z^{(k)}$ are the same.

Also, as long as the initial matrices $(\widehat{Q}^{(0)})$ are the same, this algorithm generates the same sequence $Q^{(k)}$ as the unnormalized simultaneous iteration.

For the price of a QR-factorization per iteration we get a much better conditioned sequence of basis for the space; $\operatorname{span}\left(\vec{z}_1^{(k)},\ldots,\vec{z}_n^{(k)}\right) \to \operatorname{span}\left(\vec{q}_1,\ldots,\vec{q}_n\right)$.

Simultaneous Iteration ⇔ QR-Algorithm

The QR-algorithm is **equivalent** to simultaneous iteration applied to the full set (n = m) of initial vectors, *i.e.* $Q^{(0)} = I_{m \times m}$.

We are now dealing with the full QR-factorizations, so we drop the hats on $Q^{(k)}$, and $R^{(k)}$. Further, let $\underline{Q^{(k)}}$ denote the matrices generated by the simultaneous iteration, and $\overline{Q^{(k)}}$ be the matrices generated by the QR-algorithm...

Simultaneous Iteration			Pure QR-Algorithm		
$Q^{(0)}$	=	1	$A^{(0)}$	=	Α
$\overline{Z}^{(k)}$	=	$AQ^{(k-1)}$	$Q^{(k)}R^{(k)}$	=	$A^{(k-1)}$
$Q^{(k)}R^{(k)}$	=	$Z^{\overline{(k)}}$	$A^{(k)}$	=	$R^{(k)}Q^{(k)}$
$A^{(k)}$	=	$(\underline{Q}^{(k)})^*A\underline{Q}^{(k)}$	$\underline{Q}^{(k)}$	=	$Q^{(1)}Q^{(2)}\cdots Q^{(k)}$
$\underline{R}^{(k)} = R^{(k)}R^{(k-1)}\cdots R^{(1)}$					

Table: The operations and quantities that define the Simultaneous Iteration algorithm and Pure QR-Algorithm.

Simultaneous Iteration ⇔ QR-Algorithm

Theorem

The Simultaneous Iteration algorithm and the Pure QR-algorithm generate identical sequences of matrices $\underline{R}^{(k)}$, $\underline{Q}^{(k)}$, and $A^{(k)}$, namely those defined by the QR-factorization of the kth power of A,

$$\underline{Q}^{(k)}\underline{R}^{(k)}=A^k,$$

together with the projection

$$A^{(k)} = (\underline{Q}^{(k)})^* A \underline{Q}^{(k)}.$$

This is not obvious at first glance, so let's look at the proof...

Proof: [By Induction] The base case (k=0) is trivial, for both SI and QR-Alg we immediately see that

$$A^{0} = \underline{Q}^{(0)} = \underline{R}^{(0)} = I, \quad A^{(0)} = A,$$

from which

$$A^{0} = \underline{Q}^{(0)}\underline{R}^{(0)}, \quad A^{(0)} = (\underline{Q}^{(0)})^{*}A\underline{Q}^{(0)}.$$

Proof: [By Induction] The base case (k = 0) is trivial, for both SI and QR-Alg we immediately see that

$$A^{0} = \underline{Q}^{(0)} = \underline{R}^{(0)} = I, \quad A^{(0)} = A,$$

from which

$$A^0 = \underline{Q}^{(0)}\underline{R}^{(0)}, \quad A^{(0)} = (\underline{Q}^{(0)})^*A\underline{Q}^{(0)}.$$

Now, consider k > 1 for SI: The second part of the theorem is valid by definition — $A^{(k)} = (Q^{(k)})^* A Q^{(k)}$.

Proof: [By Induction] The base case (k = 0) is trivial, for both SI and QR-Alg we immediately see that

$$A^{0} = \underline{Q}^{(0)} = \underline{R}^{(0)} = I, \quad A^{(0)} = A,$$

from which

$$A^0 = \underline{Q}^{(0)}\underline{R}^{(0)}, \quad A^{(0)} = (\underline{Q}^{(0)})^*A\underline{Q}^{(0)}.$$

Now, consider $k \ge 1$ for SI: The second part of the theorem is valid by definition — $A^{(k)} = (\underline{Q}^{(k)})^* A \underline{Q}^{(k)}$. The first part follows from

$$A^k \stackrel{\text{[1]}}{=} A\underline{Q}^{(k-1)}\underline{R}^{(k-1)}$$

[1] Follows from the inductive hypothesis $A^{k-1} = \underline{Q}^{(k-1)}\underline{R}^{(k-1)}$

Proof: [By Induction] The base case (k = 0) is trivial, for both SI and QR-Alg we immediately see that

$$A^{0} = \underline{Q}^{(0)} = \underline{R}^{(0)} = I, \quad A^{(0)} = A,$$

from which

$$A^0 = \underline{Q}^{(0)}\underline{R}^{(0)}, \quad A^{(0)} = (\underline{Q}^{(0)})^*A\underline{Q}^{(0)}.$$

Now, consider $k \ge 1$ for SI: The second part of the theorem is valid by definition — $A^{(k)} = (\underline{Q}^{(k)})^* A \underline{Q}^{(k)}$. The first part follows from

$$A^{k} \stackrel{\text{[1]}}{=} A\underline{Q}^{(k-1)}\underline{R}^{(k-1)} \stackrel{\text{[2]}}{=} \underline{Q}^{(k)}R^{(k)}\underline{R}^{(k-1)}$$

- [1] Follows from the inductive hypothesis $A^{k-1} = \underline{Q}^{(k-1)}\underline{R}^{(k-1)}$
- [2] From $Q^{(k)}R^{(k)} = Z^{(k)} = AQ^{(k-1)}$

Proof: [By Induction] The base case (k = 0) is trivial, for both SI and QR-Alg we immediately see that

$$A^{0} = \underline{Q}^{(0)} = \underline{R}^{(0)} = I, \quad A^{(0)} = A,$$

from which

$$A^0 = \underline{Q}^{(0)}\underline{R}^{(0)}, \quad A^{(0)} = (\underline{Q}^{(0)})^*A\underline{Q}^{(0)}.$$

Now, consider $k \ge 1$ for SI: The second part of the theorem is valid by definition — $A^{(k)} = (\underline{Q}^{(k)})^* A \underline{Q}^{(k)}$. The first part follows from

$$A^{k} \stackrel{\text{[1]}}{=} A\underline{Q}^{(k-1)}\underline{R}^{(k-1)} \stackrel{\text{[2]}}{=} \underline{Q}^{(k)}R^{(k)}\underline{R}^{(k-1)} \stackrel{\text{[3]}}{=} \underline{Q}^{(k)}\underline{R}^{(k)}$$

- [1] Follows from the inductive hypothesis $A^{k-1} = \underline{Q}^{(k-1)}\underline{R}^{(k-1)}$
- [2] From $Q^{(k)}R^{(k)} = Z^{(k)} = AQ^{(k-1)}$
- [3] From $R^{(k)} = R^{(k)}R^{(k-1)}\cdots R^{(1)}$

Next we consider $k \ge 1$ for QR-Alg: We verify the first part of the theorem by the sequence

$$A^k \stackrel{\text{\tiny [1]}}{=} A\underline{Q}^{(k-1)}\underline{R}^{(k-1)}$$

[1] Follows from the inductive hypothesis $A^{k-1} = \underline{Q}^{(k-1)}\underline{R}^{(k-1)}$

Next we consider $k \ge 1$ for QR-Alg: We verify the first part of the theorem by the sequence

$$A^{k} \stackrel{\text{[1]}}{=} A\underline{Q}^{(k-1)}\underline{R}^{(k-1)} \stackrel{\text{[2]}}{=} \underline{Q}^{(k-1)}A^{(k-1)}\underline{R}^{(k-1)}$$

- [1] Follows from the inductive hypothesis $A^{k-1} = \underline{Q}^{(k-1)}\underline{R}^{(k-1)}$
- [2] From the inductive hypothesis $A^{(k-1)} = (\underline{Q}^{(k-1)})^* A \underline{Q}^{(k-1)}$, multiplied from the left by $\underline{Q}^{(k-1)}$.

Next we consider $k \ge 1$ for QR-Alg: We verify the first part of the theorem by the sequence

$$A^k \stackrel{\text{\tiny [1]}}{=} A\underline{Q}^{(k-1)}\underline{R}^{(k-1)} \stackrel{\text{\tiny [2]}}{=} \underline{Q}^{(k-1)}A^{(k-1)}\underline{R}^{(k-1)} \stackrel{\text{\tiny [3]}}{=} \underline{Q}^{(k)}\underline{R}^{(k)}$$

- [1] Follows from the inductive hypothesis $A^{k-1} = \underline{Q}^{(k-1)}\underline{R}^{(k-1)}$
- [2] From the inductive hypothesis $A^{(k-1)} = (\underline{Q}^{(k-1)})^* A \underline{Q}^{(k-1)}$, multiplied from the left by $\underline{Q}^{(k-1)}$.
- [3] From $Q^{(k)}R^{(k)} = A^{(k-1)}$, $\underline{Q}^{(k)} = Q^{(1)}Q^{(2)}\cdots Q^{(k)}$, and $\underline{R}^{(k)} = R^{(k)}R^{(k-1)}\cdots R^{(1)}$

3 of 3

Finally, we verify the second part by the sequence

$$A^{(k)} \stackrel{\text{[1]}}{=} (Q^{(k)})^* A^{(k-1)} Q^{(k)}$$

[1] Follows from
$$Q^{(k)}R^{(k)} = A^{(k-1)}$$
, and $A^{(k)} = R^{(k)}Q^{(k)}$

Finally, we verify the second part by the sequence

$$A^{(k)} \stackrel{\text{[1]}}{=} (Q^{(k)})^* A^{(k-1)} Q^{(k)} \stackrel{\text{[2]}}{=} (\underline{Q}^{(k)})^* A \underline{Q}^{(k)}$$

- [1] Follows from $Q^{(k)}R^{(k)} = A^{(k-1)}$, and $A^{(k)} = R^{(k)}Q^{(k)}$
- [2] From the inductive hypothesis $A^{(k-1)} = (\underline{Q}^{(k-1)})^* A \underline{Q}^{(k-1)}$, and $\underline{Q}^{(k)} = Q^{(1)} Q^{(2)} \cdots Q^{(k)} \square$

Let's put together the pieces of the "QR-Algorithm Jigsaw Puzzle"

- The relations (from the theorem)
 - [i] $Q^{(k)}R^{(k)} = A^k$, tell us why we expect to find the eigenvectors — the QR-Algorithm constructs orthonormal bases for successive powers of A^k
 - $A^{(k)} = (Q^{(k)})^*AQ^{(k)}$ explain why we find the eigenvalues [iii] — the diagonal elements of $A^{(k)}$ are the Rayleigh coefficients of A corresponding to the columns of $Q^{(k)}$. As the columns converge to eigenvectors, the Rayleigh coefficients converge ("quadratically faster") to the corresponding eigenvalues. Since $Q^{(k)}$ converge to an orthonormal matrix, the off-diagonal elements in $A^{(k)}$ must converge to zero.

Theorem

Let the pure QR-Algorithm be applied to a real symmetric matrix A whose eigenvalues satisfy $|\lambda_1| > |\lambda_2| > \cdots > |\lambda_m|$ and whose corresponding eigenvector matrix Q has all non-singular leading principal sub-matrices. Then as $k \to \infty$, $A^{(k)}$ converges linearly with constant $\max_{1 \le j < n} \left| \frac{\lambda_{j+1}}{\lambda_j} \right|$ to $\operatorname{diag}(\lambda_1, \ldots, \lambda_m)$ and $\underline{Q}^{(k)}$ converges at the same rate to Q (mod $\pm 1 \cdot \underline{\vec{q}}_j^{(k)}$).

Next, we look into adding shifts to the QR-Algorithm in order to speed up the convergence.
